Title : The Technique of Iodometric Determination of
Peroxides in Fats.

Orig Pub: Prumysl potraviny, 1955, 6, No 12, 610-611.

Abstract: The determination of peroxides in fats is carried out in the same way as the iodometric determination of H_2O_2 , but with the application of organic solvents (chloroform, acetic acid, carbon tetrachloride). The determination is conducted in a flask equipped with a condenser, the inlet of air is prevented by a Bunsen valve. The reaction takes place in an atmosphere of CO_2 .

Title : Vitaminization of Dry Milk with L-Ascorbic Acid.

Orig Pub: Vyziva lidu, 1956, 11, No 11, 156-158.

Abstract: 200-250 mg l-ascorbic acid (I) and 100 mg Na-citrate are added per liter of milk which is then spray-dried and packed in cardboard boxes. During drying about 10% of the added I are destroyed. On prolonged storage of the vitaminized dry milk no change in milk fats and no taste deterioration take place due to the antioxidant properties of I. The reconstituted milk is recommended for infant feeding.

exception of the deodorized peanut butter, which is rancid at $PH = 15$, soybean oil, which is rancid at $PH = 10$, and cottonseed oil, which is rancid at $PH = 5$. Acidity not always characterizes the degree of rancidity of fats, it is most applicable to the analysis of cow butter. Kreis's test is important only, if the result is positive. Schmalzuss's test is useful for the establishing of a strong rancidity, and Keren's [transliteration from Russian] test is not very reliable. Colorimetric methods yielded good results. - A. Yemel'yanov.

Light scattering. I. Some factors in the measurement of light scattering in cylindrical cells. Bohoslav Sedláček (Univ. Brno, chem. CSAY; Prague, Czechoslovakia) *J. Polym. Sci. A-2*, 1954, 12(1963).—Expressions are derived for correction factors in the measurement of light scattering in cylindrical cells for parallel and convergent beams. Cylindrical cells can be used especially for the measurement of reduced intensities and the dissymetry. The accuracy of comparative measurements is satisfactory. II. A universal visual instrument. *Ibid.*, 1120-6.—A simple app. was constructed by mounting a special device on a conventional Pulfrich photometer. This app. permits the measurement of the radiation envelope from 20 to 140° and can be adapted to depolarization measurements. Exptl. results on human serum albumin and γ -globulin agree with published data. III. Measurement of the reduced intensity of liquid standards. *Ibid.*, 1591-7.—The Rayleigh consts. of CCl_4 , C_6H_6 , and CS₂ were measured for the wave length 4358 and 5460 Å. at 20° by an abs. visual method, by use of cylindrical cells and the app. described in part II. Uncorrected results are in good agreement (within 10%) with older data; results corrected for reflection of primary beams and for divergency of beams of scattered light (due to the difference between n of measured sample and of environment) approach values given by Carr and Zimm [*J. Chem. Phys.*, 1941, 9(11)]. These results prove that the main discrepancies between the old and new data are primarily due to divergency of rays of scattered light. IV. A photographic instrument for measuring light scattering. *Ibid.*, 1885-8.—A simple app. with two modifications is described: a com. photographic app. is fixed to the rotary arm of a circular stand with a scale that permits the comparative measurement of the intensity distribution of the scattered light from 50° to 140°. Instead of the photographic app., a special camera with a strip of film that almost completely surrounds the specimen can be used. The app. is also suitable for the calibration of cells. B. Hrdla

AUTHOR: Sedláček, Blahoslav

TITLE: On the Interaction of Proteins.XI. (O interakcích bílkovin.XI) The Interaction of Trypsin and Serum Albumen which has been Denatured by Heat (Interakce trypsin-serumalbumin denaturovaný teplem)

PERIODICAL: Chemické Listy, 1958, Vol.52(92), Nr 10, pp 1951 - 1955 (Czechoslovakia)

ABSTRACT: During a recent investigation of the physical and chemical properties of trypsin (Ref.1), it was found that trypsin, which under normal conditions is present in the form of a dimer in the solution, is dissociated at slightly increased temperatures, and is substantially found in the form of the monomer at 30°C. At this temperature trypsin has the maximum capacity to degrade proteins. It is known that at higher temperatures trypsin gradually loses its activity which, however, it regains on cooling. L. Gorini (Ref.2) stated that only denatured albumen can be degraded by trypsin. The authors investigated this reaction by light dispersion, especially by using the method of dissymmetry which gives a very good indication on changes in the size of the particles. The purity of the human serum albumen in a veronal-acetate buffer was

Card 1/4

CZ/8-52(82)-10-2/39

On the Interaction of Proteins.XI. The Interaction of Trypsin and Serum Albumen which has been Denatured by Heat

practically 100%. The trypsin was recrystallised several times and purified. Both compounds were filtered through a Jena crucible, and the filtrate denatured by heat. The trypsin solution was added in small quantities to the albumen solution at 35°C; this avoided any changes in the concentration of the proteins and the pH value. The intensity of the dispersed light was measured on a visual apparatus (Ref.4) at wave lengths of 5460 Å. The values of dissymmetry were defined by measuring the values R_{45} and R_{135} . It was found that during the enzymatic degradation of human serum albumen, not only a degradative reaction takes place, but aggregates are formed, the size of which exceeds the dimensions of the particles present in the solution of the heat aggregated albumen. This process is largely reversible; the heating of the solution to 80°C causes disaggregation of the particles which form again large aggregates on heating and prolonged standing. This operation was repeated five times, and the process still found to be reversible. The whole aggregation process only requires

On the Interaction of Proteins XI. The Interaction of Trypsin and Serum Albumen which has been Denatured by Heat

up to an hour, and the degradation is practically instantaneous. Values required for illustrating the observed reaction are given in Tables 1 and 2. The authors put forward the following hypothesis: the action of the trypsin causes a degradation of the denatured albumen to increasingly lower (polypeptide) aggregates. During this process some of the bonds are freed and this initiates aggregation of the trypsin-albumen complex. On further heating, these bonds are broken up by the Brownian movement. There is obviously a greater tendency to chaotisation than to arrangement of the particles which agrees with observations made. There are

TITLE: Protein interactions (O interakcích bílkovin) VII. Study of the heat denaturation of human albumin using electron microscopy (Elektronový mikroskopický studie tepelné denaturace lidského serumalbuminu)

PERIODICAL: Chemické listy, 1958, Vol 52, Nr 11, PP 2044 - 2047 + 2 plates (Czechoslovakia)

ABSTRACT: By means of electron microscope studies it was established that under the given experimental conditions the first physical stage of thermal denaturation of human serum albumin is aggregation of particles into linear chains, the individual segments of which are of a size approaching the dimensions of the molecule of the native albumin; the length of the chain usually does not exceed 2 000 Å and the most frequent length is 800 Å. In addition to straight chains, branched chains were also observed. The second stage of aggregation is agglomeration of the chains into large aggregates which become more compact with the progress of denaturation. The aggregates are of a colloidal form which precipitate from the solution. In the conclusions, it is stated that the electron microscope studies described in this paper

Card 1/3

have fully confirmed earlier results of the author (Ref.1), obtained by the method of light diffraction for systems of particles of human serum albumin aggregated as a result of denaturation by heat. In particular, it was proved, on the one hand, that there is a particular stage of aggregation (segments) into longer chains where aggregation of particles of the chains remains distinguishable even at higher degrees of aggregation and, on the other hand, that the thickness of the particles (chains) remains relatively constant at various degrees of aggregation. Of interest is also the fact that the presence of large particles has been detected during the very first phases of thermal denaturation, which indicates the existence of various types of particles in the native albumin or the considerable influence of denaturation in the interphase solution-air and experimental conditions (pH values, ion forces, ion quality, temperature, duration of the heating, etc.) is likely to yield more detailed information on the process and properties of the products obtained during denaturation

Abstract : The distinguishing feature of the proposed design consists of employing the auto-collimation scheme with double passage of the rays through the cuvette, the upper portion of which has a barrier, forming neighboring prisms with a solution and with solvent, and the lower (plane-parallel) is filled with the solvent. This increases the sensitivity, makes the instrument more compact, and by simultaneous observation of the rays passing through the upper and lower parts of the cuvette, there

SOURCE: Vojenske zdravotnicke listy, no. 5, 1965, 221-226

TOPIC TAGS: irradiation dosimetry, radiology

ABSTRACT: The amount of time spent at an x-ray center is not a good indication of the amount of radiation to which a worker was exposed. Doctors working with x-ray rarely are subjected to amounts of radiation exceeding safe limits. The most dangerous work is in perimyelography, splenoportography, and irrigoscopy. Both a film and a pocket dosimeter are good indication of the amount of exposure. Film dosimetry is very reliable. The work is based on a one-year practical test at an x-ray center. The method is very reliable. Orig. art. has: 8 figures and 1 table. [JPRS]

AUTHOR: Sedlaček, Jiří, Engineer

TITLE: Organochemical industry

PERIODICAL: Chemik, no. 2, 1960, 57-59

TEXT: The main obstacle for the development of the organochemical industry in Czechoslovakia was the insufficiently developed raw material basis and the low industrial capacity. The raw materials used so far were distillation products from bituminous coal tar, by-products obtained from the processing of brown coal at the plants imeni Stalin, ethyl alcohol obtained by fermentation, and carbide. The development of the organochemical industry in Czechoslovakia is based on the utilization of new raw materials, such as petroleum, natural gas, and coke-oven gas. The basis of raw materials required to reach the targets set by the XI Congress of the Communist Party of Czechoslovakia for the production of plastics and synthetic fibers, and for the further development of the Czechoslovakian chemical industry is intended to be created by 1965. The

Card 1/4

investment cost will be about 0.7 K^Ys per 1 K^s gross production, whereas, up to now, the investment cost averaged in the entire chemical industry 1.390 K^s per 1 K^s gross production. About 475,000,000 K^s will be saved per year by utilizing cheaper raw materials. The working productivity has to be increased by about 6 times as compared with the average productivity of the total chemical production in 1958. By 1965, the scarcity of phenols during recent years will be overcome, since plants producing phenols by the sulfonation method with a yearly capacity of 10,000 t, and by the cumene method with a yearly capacity of 20,000 t will be erected; this phenol will be used primarily for the production of caprolactam (15,000 t per year). Moreover, a plant producing ethylene glycol (10,000 t per year) by direct oxidation of ethylene without chlorine, two plants producing synthetic detergents (20,000 t alkyl aryl sulfonates, propylene tetramer, and aliphatic alcohols), a plant producing cheap acetylene, acetic acid, vinyl acetate, and chloroprene rubber, phthalic anhydride by fluidization-oxidation of naphthalene, etc are planned. Mentioned are investigations in the field of V₂O₅ catalysts, special catalyst carriers

Card 2/4

for fluidization-oxidation of hydrocarbons, production of maleic anhydride from benzene, multi-purpose utilization of xylene, production of citric acid by fermentation, phthalic acid plasticizers, coal, tar dyes (planned production in 1965: 8,000 t and 25 new types), new auxiliary agents for the textile industry, furane chemistry with a view to produce new resins, production of cyclohexyl amine and aniline by the catalytic method, etc. In the Eastern part of Slovakia a large chemical combine will be erected to process the coke gas recovered in the new metallurgical combine, where also acrylonitrile will be produced for further processing to polyacryl nitrile fibers. Further development is foreseen for the chemical plants at Bratislava, Ustí n./Labem, Spolana at Neratovice, the East-Czech chemical plant Synthesia at Pardubice, Chemka at Stražské, the Moravian chemical plant at Ostrava, the Institute of Organic Synthesis at Rybitví, the Petrochemical Institute at Nováky, the Institute of Agrotechnical Technology at Bratislava, and the Institute of Petroleum and Hydrocarbons at Bratislava. Sedláček, Jiri

Sedláček, Jiri. On systems of diagonals in convex n -gons. Casopis Pěst. Mat. 81 (1956), 157-161. 1-F/W

Let P be a convex n -gon in the plane no three diagonals of which have a common point in the interior of P . A system $S_k^{(n)}$ is a set of diagonals with exactly k points of intersection in P 's interior and such that addition to $S_k^{(n)}$ of any further diagonal introduces at least one new point of intersection. Let $f(k, n)$ be the number of different systems $S_k^{(n)}$. It is shown that

$$f(0, n) = \binom{2n-4}{n-2} (n-1), \quad f(1, n) = \frac{1}{2}(n-3)f(0, n),$$

and a more complicated formula is obtained for $f(2, n)$. The problem, for which k there exist systems $S_k^{(n)}$ and how $f(k, n)$ can be evaluated, remains unsolved for $k > 2$.

Remark on the convex polygon

Sedláček, Jiří. Eine Bemerkung über das konvexe Polygon. Časopis Pěst. Mat. 82 (1957), 349-352. (Czech. Russian and German summaries)

Let P be a convex n -gon in the plane no three diagonals of which have a common point in the interior of P . A system $S_k^{(n)}$ is a set of diagonals with exactly k points of intersection in P 's interior and such that addition to $S_k^{(n)}$ of any further diagonal introduces at least one new point of intersection. card $S_k^{(n)}$ denotes the number of elements of the system. The author proves: If $4 \leq 2k + 2 \leq n$ and $n - k - 1 \leq c \leq n + k - 3$, then there exists $S_k^{(n)}$ with card $S_k^{(n)} = c$; and, conversely, if $S_k^{(n)}$ exists, then $n - k - 1 \leq \text{card } S_k^{(n)} \leq n + k - 3$. This answers some questions raised by the author in an earlier paper [same Časopis 81 (1956), 157-161; MR 19, 161]. F. A. Behrend.

1-FIW

A source of a directed graph is a node on which no edge ends. The central concept of this paper is the *W*-basis of a finite directed graph: a subgroup which embraces all the nodes and all of whose connected components are trees, each of these trees having just one source. Such trees are called *W*-trees. The following results concerning the *W*-bases of finite acyclic graphs and finite well-directed graphs (graphs in which it is possible to go from any given node to any other given node along the edges in the direction of the arrows) are obtained. 1. Let *A* denote an acyclic graph with one or more sources and let *B* denote a subgraph of *A* whose connected components are all *W*-trees. Then *A* has a *W*-basis of which *B* is a subgraph and whose sources are all sources of *A*. 2. If corresponding to each node *w* of a finite directed graph *G* there is a *W*-basis of *G* which has *w* as its only source, then *G* is well-directed. 3. Let *G* denote a well-directed graph and *B* a non-empty subgraph of *G* whose connected components are all *W*-trees. *G* has a *W*-basis which has the same sources as *B* and of which *B* is a subgraph. 4. A directed graph *G* is well-directed if and only if corresponding to each non-empty subset *P* of the nodes of *G* there is a *W*-basis of *G* whose sources are the nodes in *P*. An application of *W*-bases to the theory of determinants is also given.
